The Haagerup planar algebra (HPA) is a subfactor planar algebra which has principal graph $H =$

Closed circles count for $\delta = \sqrt{\frac{5+\sqrt{13}}{2}} \approx 2.07$.

The Haagerup planar algebra is the smallest (in terms of δ) “exotic” planar algebra.

The Haagerup subfactor was originally constructed by Haagerup-Asaeda, and later by Izumi.

To prove the existence of the Haagerup planar algebra, without invoking the Haagerup subfactor, we

- extract information about a presentation of HPA from H .
- use this information to find a potential generator T of HPA inside $PABG(H)$.
- prove that T generates a subfactor planar algebra and this planar algebra has principal graph H .

Algorithm to evaluate a
closed diagram

An irreducible module of the annular Temperley-Lieb algebra is generated by a lowest weight element T .

If $\text{wt}(T) > 0$ then we have (for some root of unity ω)

The diagram shows a sequence of three circular diagrams representing elements in the annular Temperley-Lieb algebra. Each diagram consists of a central circle labeled T surrounded by a ring divided into six sectors. The first diagram has two sectors shaded gray and two stars on the left. The second diagram has one sector shaded gray and one star on the left. The third diagram has no shaded sectors and one star at the top. The equation is: $\star \star \text{Diagram 1} = \star \text{Diagram 2} = \dots = 0, \text{Diagram 3} = \omega T$.

If $\text{wt}(T) = 0$ we have (for some μ , $0 \leq \mu \leq \delta$)

The diagram shows a circular diagram consisting of three concentric circles. The innermost circle is labeled T . The middle and outermost rings are shaded gray. The equation is: $\text{Diagram} = \mu^2 T$.

Linear algebra

Quadratic relations

Algorithm to evaluate a closed diagram

Irreducible annular TL-modules are indexed by their low weight and an eigenvalue:

- $V^{0,\mu}$, for $\mu \in [0, \delta]$
- $V^{\ell,\omega}$, for $\omega^\ell = 1$.

Combinatorics of these modules are easy! Assuming $\delta > 2$, let's count their k -boxes:

$$\dim V_k^{0,\delta} = \frac{1}{k+1} \binom{2k}{k}, \quad \dim V_k^{0,\mu} = \binom{2k}{k}, \quad \dim V_k^{0,0} = \frac{1}{2} \binom{2k}{k}$$

$$\dim V_k^{\ell,\omega} = \binom{2k}{k-\ell}$$

Linear algebra

Quadratic relations

Algorithm to evaluate a
closed diagram

$$HPA \simeq V^{0,\delta} \oplus V^{4,-1} \oplus V^{6,?} \oplus \dots$$

Therefore, to present the Haagerup planar algebra, we need a generator T which has eight strands, and for which

$$\star \left(\begin{array}{c} \text{loop on top-left} \\ \star \quad \star \\ T \end{array} \right) = \star \left(\begin{array}{c} \text{loop on top} \\ \star \quad \star \\ T \end{array} \right) = \dots = 0, \left(\begin{array}{c} \star \\ \star \quad \star \\ T \end{array} \right) = -T.$$

In $PABG(H)_4$ (which is 375-dimensional), we perform a similar annular Temperley-Lieb module analysis. We find there is a four-dimensional subspace of low weight four, eigenvalue -1 elements.

A potential generator T in $PABG(H)_4$

Linear algebra

Quadratic relations

Algorithm to evaluate a
closed diagram

There is a unique element T in $PABG(H)_4$ satisfying these annular relations, and also

$\in \text{span}\{TL, T\}$.

But how do we show that the planar algebra generated by T is the Haagerup planar algebra?

How to show $PA(T)$ is the Haagerup planar algebra

generated by T

Linear algebra

Quadratic relations

Algorithm to evaluate a
closed diagram

We need to show that $\dim PA(T)_0 = 1$; then we know $PA(T)$ is a subfactor planar algebra with $\delta = \sqrt{\frac{5+\sqrt{13}}{2}}$ and finite depth, and so it must have principal graph H .

Our goal is to show that any closed diagram is a multiple of the empty diagram.

We do this by giving a short list of “quadratic” relations, and making a graph-theory argument to show these suffice.

We prove these relations with linear algebra.

Now we're ready to show

Theorem

$PA(T)_0$ is one dimensional.

Proof by induction.

This theorem says that any closed diagram is a multiple of the empty diagram.

Any closed diagram with no T s is a Temperley-Lieb diagram.

Any closed diagram with one T has a strand connecting T to itself.

Any closed diagram involving two or more T s can be replaced by a diagram with fewer T s, using the quadratic relations above. \square

Linear algebra
Quadratic relations

Algorithm to evaluate a
closed diagram

This last step – any closed diagram involving two or more T s can be replaced by a diagram with fewer T s, using the quadratic relations – requires some justification.

Certainly, if any two T s in the closed diagram are attached by three adjacent strands, it is easy to see that the diagram can be replaced by [a weighted sum of] diagrams involving fewer T s.

But what if the diagram only has T s connected by one or two strands? Then we want to change it around until it has two T s connected by three strands.
